1. Introduction

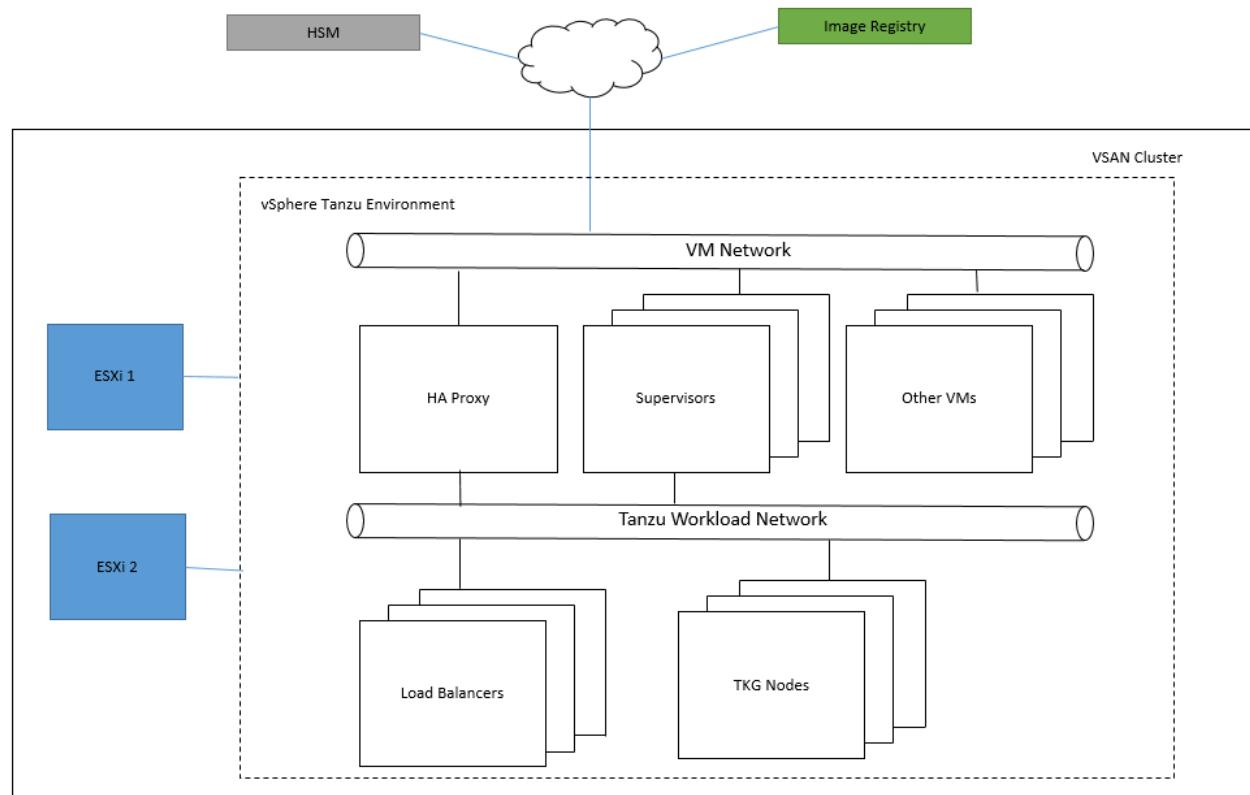

VMware vSphere with Tanzu Kubernetes cluster integrates with an nShield Hardware Security Module (HSM), using the nShield Container Option Pack (nSCOP).

VMware vSphere with Tanzu uses your existing vSphere environment to deliver Kubernetes clusters at a rapid pace. Developers can build, launch, and scale container-based web applications in the vSphere environment. nSCOP allows application developers, in the container-based environment of vSphere with Tanzu, to access the cryptographic functionality of an HSM.

1.1. Integration architecture overview

1.1.1. vSphere Tanzu Cluster and HSM

In this integration, a vSphere Tanzu Kubernetes cluster is deployed in a VMware vSAN cluster. Container images are downloaded from a Docker registry.

The following hosts are created:

- HA-Proxy virtual appliance for provisioning Load balancers.
- Supervisors virtual machines.

- Load balancers.
- TKG nodes.

For more information on how to deploy a VMware Tanzu Kubernetes cluster see your VMware documentation.

1.1.2. Container images

Two container images were created for the purpose of this integration: a hardserver container, and an application container. These images are stored in an external registry:

- nshield-hwsp

A hardserver container image that controls communication between the HSM(s) and the application containers. One or more hardserver containers are required per deployment, depending on the number of HSMs and the number and types of application containers.

- nshield-app

Application container images to run nShield commands. They are Red Hat Universal Base Image containers, in which Security World software is installed.

You can also create containers that contain your application. For instructions, see the *nShield Container Option Pack User Guide*.

1.2. Product configurations

We have successfully tested the integration of an nShield HSM with VMware vSphere Tanzu in the following configurations:

Container Base OS	vSphere Tanzu	VMware	nShield HSM	nShield Image	nShield Firmware	nShield Software	nSCOP
RHEL, CentOS, Ubuntu	7.0.2	7.0.2	Connect XC	12.60.10	12.50.11	12.71.0	1.1.1

1.3. Requirements

1.3.1. Before starting the integration process

Familiarize yourself with:

- The documentation for the nShield HSM.
- The *nShield Container Option Pack User Guide*.
- The documentation and setup process for vSphere with Tanzu.

2. Procedures

2.1. Prerequisites

Before you can use nSCOP and pull the nSCOP container images to the external registry, complete the following steps:

1. Install VMware vSphere Tanzu in a VMware vCenter environment. See the documentation provided by VMware.
2. Set up the HSM. See the *Installation Guide* for your HSM.
3. Configure the HSM(s) to have the IP address of your container host machine as a client. This can be a VM running Red Hat.
4. Load an existing Security World or create a new one on the HSM. Copy the Security World and module files to your container host machine at a directory of your choice. Instructions on how to copy these two files into a persistent volume accessible by the application containers are given when you create the persistent volume during the deployment of the TKG cluster.
5. Installed nSCOP and created containers that contain your application. For the purpose of this guide you will need the nSCOP hardserver container and your application container. In this guide we will refer to them as **nshield-hwsp** and **nshield-app** containers. For instructions, see the *nShield Container Option Pack User Guide*.

For more information on configuring and managing nShield HSMs, Security Worlds, and Remote File Systems, see the *User Guide* for your HSM(s).

2.2. Push the nSCOP container images to an internal Docker registry

You will need to register the nSCOP container images you created to a Docker registry so they can be used when you deploy Kubernetes pods into the Tanzu Kubernetes Cluster you will create later. In this guide, the external registry is `<docker-registry-address>`. Distribution of the nSCOP container image is not permitted because the software components are under strict export controls.

To deploy an nSCOP container images for use with VMware vSphere Tanzu:

1. Log in to the container host machine server as root, and launch a terminal window. We assume that you have built the nSCOP container images in this host and that they are available locally in Docker. They are: **nshield-hwsp:12.71** and **nshield-app:12.71**.
2. Log in to the Docker registry.

```
% docker login -u YOURUSERID https://<docker-registry-address>
```

3. Register the images:

a. Tag the images:

```
% sudo docker tag nshield-hwsp:12.71" <docker-registry-address>/nshield-hwsp  
% sudo docker tag nshield-app:12.71" <docker-registry-address>/nshield-app
```

b. Push the images to the registry:

```
% sudo docker push <docker-registry-address>/nshield-hwsp  
% sudo docker push <docker-registry-address>/nshield-app
```

c. Remove the local images:

```
% sudo docker rmi <docker-registry-address>/nshield-hwsp  
% sudo docker rmi <docker-registry-address>/nshield-app
```

d. List the images:

```
% sudo docker images
```

e. Pull the images from the registry:

```
% sudo docker pull <docker-registry-address>/nshield-hwsp  
% sudo docker pull <docker-registry-address>/nshield-app
```

f. List the images:

```
% sudo docker images
```

2.3. Deploy a TKG cluster

You will use the namespace you created when you deployed vSphere Tanzu to deploy out a TKG - a Tanzu Kubernetes cluster. You will do this from the container host machine. Make sure the **kubectl** and **kubectl-vsphere** commands are downloaded and available to be used in that machine. We will call the namespace **tanzu-ns**.

2.3.1. Log in to the namespace context

Use the **kubectl-vsphere** login command and set the server to the Supervisor Control Plane API Server IP address. This is the first IP address you use for the load balancers when you deployed the HA proxy server during the vSphere Tanzu setup.

```
% kubectl-vsphere login --insecure-skip-tls-verify --vsphere-username administrator@vsphere.local  
--server=https://<load_balancer_ip>
```

```
Password:*****  
Logged in successfully.
```

```
You have access to the following contexts:
```

- * xxx.xxx.xxx.xxx
- * tanzu-ns

If the context you wish to use is not in this list, you may need to try logging in again later, or contact your cluster administrator.

To change context, use 'kubectl config use-context <workload name>'

```
% kubectl config use-context tanzu-ns
```

```
Switched to context "tanzu-ns".
```

2.3.2. Verify the control plane nodes and the storage class

Check that the control plane nodes are in a ready state, and that the storage policy assigned to the namespace earlier appears as a storage class. It is also useful to verify that the TKG virtual machine images are visible and that the content library used for storing the images has synchronized successfully.

```
% kubectl get nodes
```

NAME	STATUS	ROLES	AGE	VERSION
4237574fb12b83b63026e6cc20abb152	Ready	master	28m	v1.18.2-6+38ac483e736488
4237c4c2761f4810a7794fc2ccb7433d	Ready	master	28m	v1.18.2-6+38ac483e736488
4237eb7fea870a051ae56eb564083bcb	Ready	master	28m	v1.18.2-6+38ac483e736488

```
% kubectl get sc
```

NAME	PROVISIONER	RECLAIMPOLICY	VOLUMEBINDINGMODE	ALLOWVOLUMEEXPANSION	AGE
vsan-default-storage-policy	csi.vsphere.vmware.com	Delete	Immediate	true	28m

```
% kubectl get virtualmachineimages
```

NAME	VERSION	OSTYPE
ob-15957779-photon-3-k8s-v1.16.8---vmware.1-tkg.3.60d2ffd	v1.16.8+vmware.1-tkg.3.60d2ffd	vmwarePhoton64Guest
ob-16466772-photon-3-k8s-v1.17.7---vmware.1-tkg.1.154236c	v1.17.7+vmware.1-tkg.1.154236c	vmwarePhoton64Guest
ob-16545581-photon-3-k8s-v1.16.12---vmware.1-tkg.1.da7afe7	v1.16.12+vmware.1-tkg.1.da7afe7	vmwarePhoton64Guest

2.3.3. Create a manifest file for the TKG deployment

You create a TKG cluster in vSphere with Tanzu using a **yaml** manifest file, which contains the following information:

- The name of the cluster.
- The number of control plane nodes.
- The number of worker nodes.
- The size of the nodes from a resource perspective (**class**).
- Which storage class to use (**storageClass**).
- Which image to use for the nodes (**version**).

The following example specifies:

- A single control plane node.
- 2 worker nodes.
- Uses image version 1.17.7.

This use of the version number is a shorthand to specify which Photon OS image to use. Note the indentation. It needs to be just right for the manifest to work.

cluster.yaml

```
apiVersion: run.tanzu.vmware.com/v1alpha1
kind: TanzuKubernetesCluster
metadata:
  name: tkg-cluster
spec:
  topology:
    controlPlane:
      count: 1
      class: best-effort-small
      storageClass: management-storage-policy-single-node
    workers:
      count: 2
      class: best-effort-small
      storageClass: management-storage-policy-single-node
  distribution:
    version: v1.17.7
```

To learn more about the resources assigned to the various classes, list them by using the following command:

```
% kubectl get virtualmachineclass
```

NAME	AGE
best-effort-2xlarge	2d16h
best-effort-4xlarge	2d16h
best-effort-8xlarge	2d16h
best-effort-large	2d16h
best-effort-medium	2d16h
best-effort-small	2d16h
best-effort-xlarge	2d16h
best-effort-xsmall	2d16h
guaranteed-2xlarge	2d16h
guaranteed-4xlarge	2d16h
guaranteed-8xlarge	2d16h
guaranteed-large	2d16h
guaranteed-medium	2d16h
guaranteed-small	2d16h
guaranteed-xlarge	2d16h
guaranteed-xsmall	2d16h

To get more information about a specific class, use the **describe** command:

```
% kubectl describe virtualmachineclass guaranteed-small
```

2.3.4. Apply the TKG manifest and monitor the deployment

1. Deploy the TKG cluster by applying the manifest:

```
% kubectl apply -f cluster.yaml  
tanzukubernetescluster.run.tanzu.vmware.com/tkg-cluster created
```

2. Check if cluster has been provisioned:

```
% kubectl get cluster  
  
NAME      PHASE  
tkg-cluster  Provisioned
```

3. Check the deployment of the cluster:

```
% kubectl get tanzukubernetescluster  
  
NAME      CONTROL PLANE  WORKER  DISTRIBUTION          AGE      PHASE  
tkg-cluster  1           2        v1.17.7+vmware.1-tkg.1.154236c  3m7s    creating
```

You can then use a variety of commands to monitor the deployment. The **describe** command can be long and you can use it repeatedly to monitor the TKG cluster deployment status. It contains useful information, such as the use of Antrea as the CNI, node and VM status, Cluster API endpoint from our load balancer, frontend network range of IP addresses.

```
% kubectl describe tanzukubernetescluster
```

You should see the cluster in the **running** phase if it was deployed successfully.

```
% kubectl get tanzukubernetescluster
```

NAME	CONTROL PLANE	WORKER	DISTRIBUTION	AGE	PHASE
tkg-cluster	1	2	v1.17.7+vmware.1-tkg.1.154236c	11m	running

2.3.5. Log out then log in to TKG cluster context

The previous stages were carried out in the context of a namespace in the vSphere with Tanzu Supervisor cluster. The next step is to log out from the namespace context, and log in to the TKG guest cluster context. This allows you to direct **kubectl** commands at the TKG cluster API server.

1. Log out of the namespace:

```
% kubectl-vsphere logout
```

Your KUBECONFIG context has changed.
The current KUBECONFIG context is unset.
To change context, use 'kubectl config use-context <workload name>'
Logged out of all vSphere namespaces.

2. Log in to the cluster:

```
% kubectl-vsphere login --insecure-skip-tls-verify --vsphere-username administrator@vsphere.local  
--server=https://<load_balancer_ip> --tanzu-kubernetes-cluster-namespace tanzu-ns --tanzu-kubernetes-cluster-name  
tkg-cluster
```

Password: *****
Logged in successfully.

You have access to the following contexts:
xxx.xxx.xxx.xxx
tanzu-ns
tkg-cluster

If the context you wish to use is not in this list, you may need to try logging in again later, or contact your cluster administrator.

To change context, use 'kubectl config use-context <workload name>'

3. Set the context:

```
% kubectl config use-context tkg-cluster
```

Switched to context "tkg-cluster".

2.3.6. Validate the TKG cluster context

You can run some `kubectl` commands to verify that you are now working in the correct context. If you display the nodes, you should see the 1 x control plane node and the 2 x worker nodes specified in the manifest when you deployed the cluster. You should also be able to display all the pods deployed in the cluster and observe both the Antrea agents for networking and CSI node agents for storage. This is also a good opportunity to check that everything has entered a Ready/Running state in the TKG cluster.

```
% kubectl get nodes
```

NAME	STATUS	ROLES	AGE	VERSION
tkg-cluster-control-plane-m62jn	Ready	master	28m	v1.17.7+vmware.1
tkg-cluster-workers-djqql-b45c55588-59wz2	Ready	<none>	28m	v1.17.7+vmware.1
tkg-cluster-workers-djqql-b45c55588-c52h7	Ready	<none>	28m	v1.17.7+vmware.1

```
% kubectl get pods -A
```

NAMESPACE	NAME	READY	STATUS	RESTARTS
AGE				
kube-system	antrea-agent-7zphw	2/2	Running	0
2m23s	antrea-agent-mvczg	2/2	Running	0

2m23s				
vmware-system-csi				
2m23s				

This output shows that the TKG cluster is deployed in vSphere with Tanzu.

2.4. Deploy nSCOP into the TKG cluster

When the Tanzu Kubernetes Cluster has been deployed, it is time to deploy the nSCOP containers as pods into the cluster and test the nSCOP functionality inside the cluster.

2.4.1. Create the registry secrets inside the TKG cluster

At the beginning of our process we created nSCOP Docker containers and we pushed them to our internal Docker registry. Now it is necessary to let the TKG cluster know how to authenticate to that registry.

1. Log in to the TKG cluster:

```
% kubectl-vsphere login --insecure-skip-tls-verify --vsphere-username administrator@vsphere.local  
--server=https://<load_balancer_ip> --tanzu-kubernetes-cluster-namespace tanzu-ns --tanzu-kubernetes-cluster-name  
tkg-cluster
```

<load_balancer_ip> is the IP address used by the cluster namespace.

2. Set the context to the TKG cluster:

```
% kubectl config use-context tkg-cluster
```

3. Create the secret in the cluster:

```
% kubectl create secret generic regcred --from-file=.dockerconfigjson=/home/<YOUR USER ID>/.docker/config.json  
--type=kubernetes.io/dockerconfigjson
```

4. Check if the secret was created

```
% kubectl get secret regcred --output=yaml
```

2.4.2. Create the configuration map for the HSM details

1. Edit the following template **yml** file for your HSM:

configmap yaml file

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: config
data:
  config: |
    syntax-version=1

    [nethsm_imports]
    local_module=1
    remote_esn=BD10-03E0-D947
    remote_ip=10.194.148.36
    remote_port=9004
    keyhash=2dd7c10c73a3c5346d1246e6a8cf6766a7088e41
    privileged=0
```

2. Create the configuration map:

```
% kubectl apply -f configmap.yaml
configmap/config created
```

3. Verify that the configuration map was created:

```
% kubectl describe configmap/config

Name:         config
Namespace:    default
Labels:       <none>
Annotations:
Data

config:
syntax-version=1

[nethsm_imports]
local_module=1
remote_esn=BD10-03E0-D947
remote_ip=10.194.148.36
remote_port=9004
keyhash=2dd7c10c73a3c5346d1246e6a8cf6766a7088e41
privileged=0

Events:  <none>
```

2.4.3. Create the cluster persistent volumes in the TKG cluster

1. Create the `/opt/nfast/kmdata/local` directory in your host machine and copy the Security World and module files to it.

Do this before you proceed with the creation of the persistent volume.

2. Edit the following example `yaml` file to create and claim the persistent volume:

persistent_volume_kmdata_definition yaml File

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: nfast-kmdata
  labels:
    type: local
spec:
  storageClassName: manual
  capacity:
    storage: 16
  accessModes:
    - ReadWriteMany
  persistentVolumeReclaimPolicy: Retain
  hostPath:
    path: /opt/nfast/kmdata
```

persistent_volume_kmdata_claim Yaml File

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name : nfast-kmdata
spec:
  accessModes:
    - ReadWriteMany
  storageClassName: local-storage
  resources:
    requests:
      storage: 16
  storageClassName: manual
```

3. Apply the definition file to the cluster:

```
% kubectl apply -f persistent_volume_kmdata_definition.yaml
persistentvolume/nfast-kmdata created
```

4. Verify the persistent volume has been created:

```
% kubectl get pv
NAME          CAPACITY   ACCESS MODES  RECLAIM POLICY  STATUS     CLAIM           STORAGECLASS  REASON
AGE
nfast-kmdata   16         RWO          Retain        Available   
```

5. Create the claim:

```
% kubectl apply -f persistent_volume_kmdata_claim.yaml
persistentvolumeclaim/nfast-kmdata created
```

6. Verify the claim has been created:

```
% kubectl get pvc
NAME          STATUS    VOLUME      CAPACITY   ACCESS MODES  STORAGECLASS  AGE
nfast-kmdata  Bound     nfast-kmdata  1G         RWO          manual        61m

% kubectl get pv
NAME          CAPACITY   ACCESS MODES  RECLAIM POLICY  STATUS    CLAIM
AGE
nfast-kmdata  1G         RWO          Retain        Bound      default/nfast-kmdata  manual
67m
```

2.4.4. Deploy the nSCOP pod with your application

Create a [yaml](#) file that defines how to launch the hardserver and your application container into the cluster.

The examples below were created to show how you can talk to the HSM from inside the Kubernetes pod. Each example shows how to execute the following commands:

- [enquiry](#)
- [nfmkminfo](#)
- [sigtest](#)

2.4.4.1. Populate the persistent volume with the world and modules file

1. Before running any of the applications, update [/opt/nfast/kmdata/local](#) in the persistent volume with the latest Security World and module files.

To do this, create a [yaml](#) file to run a pod that gives access to the persistent volume so these files can be copied.

The following example shows how to get access to the persistent volume.

persistent_volume_kmdata_populate.yaml

```
kind: Pod
apiVersion: v1
metadata:
  name: nscop-populate-kmdata
  labels:
    app: nshield
spec:
  imagePullSecrets:
    - name: regcred
  containers:
    - name: nscop-kmdata
      command:
        - sh
        - '-c'
        - sleep 3600
      image: <docker-registry-address>/nshield-app
      ports:
        - containerPort: 8080
          protocol: TCP
      resources: {}
  volumeMounts:
    - name: nscop-kmdata
      mountPath: /opt/nfast/kmdata
    - name: nscop-sockets
      mountPath: /opt/nfast/sockets
  securityContext: {}
volumes:
  - name: nscop-config
    configMap:
      name: config
      defaultMode: 420
  - name: nscop-hardserver
    emptyDir: {}
  - name: nscop-kmdata
    persistentVolumeClaim:
      claimName: nfast-kmdata
  - name: nscop-sockets
    emptyDir: {}
```

2. Deploy the pod:

```
% kubectl apply -f persistent_volume_kmdata_populate.yaml
```

3. Check if the pod is running:

```
% kubectl get pods
```

You should see that the deployment is taking place. Wait 10 seconds and run the command again until the status is Running.

If there are errors, run the following command to check what went wrong:

```
% kubectl describe pod nscop-populate-kmdata
```

4. Copy the module file to */opt/nfast/kmdata/local* in the pod:

```
% kubectl cp /opt/nfast/kmdata/local/module_BD10-03E0-D947 nscop-populate-kmdata:/opt/nfast/kmdata/local/.
```

5. Copy the Security World file to `/opt/nfast/kmdata/local` in the pod:

```
% kubectl cp /opt/nfast/kmdata/local/world nscop-populate-kmdata:/opt/nfast/kmdata/local/.
```

6. Check if the files are in the persistent volume

```
% kubectl exec nscop-populate-kmdata -- ls -al /opt/nfast/kmdata/local  
total 68  
drwxr-xr-x 2 root root 4096 Sep 20 18:40 .  
drwxr-xr-x 3 root root 4096 Dec 16 2020 ..  
-rwxrwxrwx 1 root 1001 3488 Sep 20 18:40 module_BD10-03E0-D947  
-rwxrwxrwx 1 root 1001 39968 Sep 20 18:40 world
```

2.4.4.2. enquiry

This example shows how to run the `enquiry` command.

pod_enquiry_app.yaml

```
kind: Pod
apiVersion: v1
metadata:
  name: nscop-test-enquiry
  labels:
    app: nshield
spec:
  imagePullSecrets:
    - name: regcred
  containers:
    - name: nscop
      command:
        - sh
        - '-c'
        - /opt/nfast/bin/enquiry && sleep 3600

```

<*docker_registry-address*> is the address of your internal Docker registry server.

1. Deploy the pod

```
% kubectl apply -f pod_enquiry_app.yaml
```

2. Check that the pod is running:

```
% kubectl get pods
```

You should see that the deployment is taking place. Wait 10 seconds and run the command again until the status is Running.

If there are errors, run the following command to check what went wrong:

```
% kubectl describe pod nscop-test-enquiry
```

3. Check if the **enquiry** command runs:

```
% kubectl logs pod/nscop-test-enquiry nscop

ABOUT ENTRUST CORPORATION

Entrust keeps the world moving safely by enabling trusted identities, payments, and data protection. Today more than ever, people demand seamless, secure experiences, whether they're crossing borders, making a purchase, accessing e-government services, or logging into corporate networks. Entrust offers an unmatched breadth of digital security and credential issuance solutions at the very heart of all these interactions. With more than 2,500 colleagues, a network of global partners, and customers in over 150 countries, it's no wonder the world's most entrusted organizations trust us.

ENTRUST
SECURING A WORLD IN MOTION
